Environmental pollution in some regions of Central- and Eastern Europe has reached the point where the data are sufficient to indicate that the health of their inhabitants has deteriorated. In line with the recommendations stemming from the WHO European Charter for Environment and Health, the WHO Regional Office for Europe, through the European Centre for Environment and Health, fosters the dialogue between the respective national authorities responsible for environmental management and public health administration at the national, regional and local level.

Through a Trust Fund arrangement with the Government of The Netherlands, technical assistance activities are carried out by the European Centre for Environment and Health in the form of National Integrated Programmes on Environment and Health with Poland, the Czech Republic, the Slovak Republic and Hungary.

The National Integrated Programmes are addressed to:

- establish more reliable linkages between environmental factors and the health of affected population groups;
- improve the quality of monitoring data on food and soil contamination through interlaboratory tests and unified analytical methods; and
- train chronic disease epidemiologists to deal with the major environmental health problems arising from exposure to environmental contamination.

# The effect of environmental factors on the health status of population in the Eastern Slovakia Lowland

Information about fulfilment according to the universal frame  
September 1992

## I. General Data

### 1. Goals:

- to identify the chosen risk factors in working conditions of the plants Chemko Strážske and Bukóza Vranov as well as those in living conditions of the Eastern Slovakia Lowland population.
- to estimate their part in the people health status,
- to determine character, measure and range of environmental pollution in the Eastern Slovakia Lowland (ESL), to propose directed precautions for protection of people health and to determine their priority,
- to improve the methodology of epidemiologic examinations, ecological sanitary monitoring, analytical techniques and information system.

#### 1.1. Characteristics of the territory

The Eastern Slovakia Lowland represents an important part of East Slovakia regarding the hygienic point. Administratively, ESL belongs into the districts Michalovce(Mi), Trebišov (Tv), Vranov nad Topľou (Vv) and Humenné (Hn). The area of the districts is 5,387 km<sup>2</sup>, out of which the ESL represents about 1,600 km<sup>2</sup>, i.e. 30 % predominantly in southern part. 416,000 inhabitants live in these districts. The range mountains Nízke Beskydy and Vihorlat in the north and Slanske vrchy (hills) in the west demarcate the lowland. The lowland continues towards the east and south across the frontiers CSFR to Transcarpathian Ukraine and Hungary.

Originally swampy and flooded territory with high number of streams (Topľa, Ondava, Laborec, Uh, Latorica, Bodrog, Tisa) was the region with endemic incidence of malaria by the end of 50's.

The large hydromelioration treatments (realized till now) and transformation to intensive utilization of agricultural soil created here the second most important agricultural region in Slovakia. Important centres of recreation near water also arose (Zemp-

línska Šírava, Vinianske lake as well as the near basin Veľká Do-maša).

Within the 50's and 60's the plants of chemical and wood industry (Chemko Strážske, Bukóza Vranov, Chemlon Humenné) began to be built in the central part along the rivers without appropriate hygienic and ecological precautions for environmental protection. Besides air pollution (dust,  $\text{SO}_2$ ,  $\text{NO}_x$ , mercaptanes, formaldehyde, PAU, benzene) also a wide contamination of water, soil as well as food-chain with pollutants especially of organic origin - polychlorinated biphenyls (PCB), formaldehyde, nitrogenous compounds and others occurred.

Early in the 70's a large energetic source for solid fuel and mazut - The Power plant - Vojany with chimneys 200 and 300 m high was built here, too.

Contamination of water and soil with agrochemicals and from animal production appears to be of great importance.

For the pollutant spreading it is important that predominant direction of wind is from the north, above sea level rapidly drops from the north towards the south (Streda nad Bodrogom - the lowest region in CSFR), and rivers flow from the north and east towards the south.

On the basis of the present data about risk factors in living and working conditions of ESL, we chose the region where the health of inhabitants may be unfavourably influenced by the specific risk from industrial and agricultural production, i.e. exposed region, and that where these risk factors are not expected, i.e. comparative region. See the map.

Exposed region represents a larger part of the districts Trebišov and Michalovce and the southern parts of the districts Vranov nad Topľou and Humenné. In the region there are 9 towns, 128 villages with about 252,400 inhabitants.

Comparative region is situated in the north-east part of the district Michalovce - the area surrounding the town Sobrance. In this region there are 1 town, 54 villages with about 29,200 inhabitants.

1.2. Above 416,000 inhabitants live in 4 districts reaching into the ESL territory. In exposed region there are about 250,000 inhabitants, what represents about 61 % out of the total number of inhabitants of the given districts.

1.3. The complex clinical-epidemiological study of the people health status in this region has not been done yet. Partial monitoring performed by the former district and regional authorities, LPS (medical second opinion board) and HS as well as comparison of the data published by the medical statistics show especially:

- higher incidence of congenital developmental diseases (e.g. Potter's syndrome),
- nitrate methemoglobinemia in infants,
- increase in the incidence of tumorous diseases,
- higher incidence of respiratory disease (a chosen set of children from the town Strážske situated close to the Chemical works - Chemko Strážske).

The PCB findings in human milk and biological materials indicate the relationship of people exposure to PCB in their environment.

1.4. In the second stage of the project it should be focused on:

- a) introducing a monitoring system of air pollution (non-specific and specific contaminants),
  - directed monitoring of contamination of water, soil and foodstuffs with foreign substances (PCB, metals, metalloids, nitrogenous compounds) as well as the presence of substances with bio-positive action on the health in these environmental factors (e.g. selenium, etc.)
  - b) - directed monitoring of the life way of inhabitants (nutrition, alcohol, smoking)
  - c) - Continuation in monitoring the PCB and heavy metals in human milk, biological and necroptic materials,
    - continuation in monitoring the health status of inhabitants with more detailed view to the diseases given in item 1.3.

## 2. 0. Methods

2.1. In the first phase of our study, the socio-demographic data, data on environmental pollution and the health status of inhabitants have been used.

The socio-demographic data were obtained from individual departments of the Sloval Statistic Office and Institute of Medical Information and Statistics.

The data on the number of inhabitants are for the present pro-

claimed preliminary results for 1991.

The data on the environmental factors were gained predominantly from our measurements performed by the Hygienic service. Supplementing data were given by SHMÚ and Water and Sewerage Works.

The data on the health status of inhabitants were gained as follows:

- a) mortality-rate - from the Slovak registry of the Slovak Statistical Office,
- b) mortality-rate concerning prenatal and postnatal period - from the registry of neonatal departments of hospitals,
- c) data on the disease rate - from the appropriate departments of hospitals.

In tumorous diseases it is a case of preliminary data that are verified in the National Oncologic Institute in Bratislava.

2.2. Specialists from the Institutes of Hygiene and Epidemiology in cooperation with physicians of LPS and specialized departments of SIHE in Košice participated in elaboration of the study. Coordinator of the study is SIHE Košice.

2.3. Data were processed in the Ist and IIInd quarter of 1992.

## II. The study scope

### 3.0. Socio-demographic data and infrastructure of health care

3.1. In exposed region there are 128 municipalities. Out of the total number of inhabitants in this region 252,383 - 40 % live in the country and 60 % in towns. Out of 9 towns 2 have above 30,000 inhabitants, one town above 20,000 and 6 within the range of 4,000 to 10,000.

In comparative region (Sobrance, Michalovce districts) situated in the north-east area of the lowland there are one town with 5,754 inhabitants and 54 villages with 23,478, thus, 80 % inhabitants live in villages.

3.2. Division of inhabitants in the region monitored according to their age and sex is given in tables 3.2.1. and 3.2.2.

3.3. Tables 3.3.1. and 3.3.2. show division of economically active inhabitants according to sectors. From the given review it follows

that in exposed and comparative regions 28 % and 23 % inhabitants are employed in industry, respectively. More inhabitants in comparative region work in agriculture (26 %) than in exposed one (15 %), what is a significant difference.

3.5. Data on the average wages per a month are given in table 3.5. There were available only regional data. <sup>re</sup> The average wage per a month is given on a calculation per physical persons and per persons of recalculated state of economically active ones.

3.6. Consumption of alcohol and cigarettes - table 3.6. - data obtained from the Slovak Statistic Office in Košice on the basis of reports from commercial network. They were available only on a recalculation per inhabitants of the East Slovakia region.

Regarding a rather widespread production of wines and distilled liquor in ESL the given data could not be valid.

3.7. Tables 3.7.1., 3.7.2. and 3.7.3. inform about the infrastructure of health care.

#### 4. Analysis of the environmental data

##### 4.1. Air pollution - tab. 4.1.

The largest industrial sources of air pollution are concentrated in the northern part of the region - Bukóza Vranov, Chemko Strázske, Power Plant (PP)-Vojany is situated more southward. A review of emissions from the main sources of air pollution is given in table.

##### Characteristic of air pollution sources

Sources according to the character of emitted pollutants may be divided into:

- a) sources polluting with products of coal burning at production of heat and electric power. The most important are:
  - Power plant Vojany - the largest sources of pollution,
  - Heating plants: Chemko Strázske, Bukóza Vranov, Chémion Humenné, Vihorlat Sníma, Food works Trebišov.

This group pollutes air with oxides of sulfur, nitrogen, carbon monooxide, ash with toxic metal content (As,Cd) and soot.

- b) sources polluting industrial production .

The most important are:

Chemko Strážske - Chemical works - emitting especially cyclohexane, cyclohexanone, benzene, formaldehyde, hydrocarbons<sup>w</sup>, methanol, dust of combined fertilizer NPK, soda dust.

Bukóza Vranov - Wood works - emitting especially hydrogen sulfide, methylmercaptan, dimethylsulfide, dimethyldisulfide, fural, sodium sulfate, calcium sulfate.

Chemlon Humenné - dinyl

Cement works Bystré - cement dust

c) agricultural sources of pollution:

- local air polluting sources especially of smell origin are represented by large-scale fattening pig houses. The main pollutants are: ammonia, mercaptans, hydrogen sulfide.

Commentary to tabular part of the part 4.1.1.

The dust drop is measured by the Institutes of Hygiene and Epidemiology Trebišov and Humenné in the areas of PP Vojany and the town Humenné, respectively.

The most polluted localities appear to be the villages Beša, Drahňov, V.Kapušany, Vojany, where portion of overlimited values represents 20-40 %. It is a case of vicinity of power plant that is influenced by the secondary dustiness from the dry parts of ash matter storage under windy conditions. In the selected checkpoints the metal content (Pb, Cd, V) in dust drop was monitored. Their limiting values has not been exceeded (according to the limits valid in Germany).

In the checkpoints in Humenné exceeding of NPK occurred only in 2 % results.

Concentrations of SO<sub>2</sub> and NO<sub>x</sub> were monitored in the northern part of the ESL territory - close to the plants Chemko Strážské, Chemlon Humenné and Bukóza Vranov. Overlimits of allowed values have been recorded in SO<sub>2</sub> in Vranov nad Topľou and in NO<sub>x</sub> at the village Olhé Klčovo.

It is necessary to mention that results in most cases have not been gained by the continual measurement; only at certain time intervals. An exception appears to be results of HMÚ from the area Strážske. The data about performed measurements are given in tabular review.

Measurements of specific pollution were carried out only in the area close to the plant Bukóza Vranov nad Topľou. Sulfur-containing compounds (hydrogen sulfide, methylmercaptan, dimethylsulfide) were measured. It was a discontinual, short-term determination of concentrations during January - October 1991.

Measurement were carried out by the Research Institute for Petrochemistry in Prievidza. Overlimits of allowed values for dimethylsulfide has been found in all localities, whereas with exception of one locality (Nižný Hrušov) the sample numbers above NPK represented 33-100 %.

It is necessary to state that results of measurements of air pollution (amount of contaminants, time realization of measurements) appear to be insufficient for objective estimation of effects on environment in such significant sources as the PP Vojany, Chemko Strázske and Bukóza Vranov nad Topľou. Especially, in a case of the latter two, interactions of various organic substances emitted in air from production processes and subsequent rise of more toxic contaminants could not be excluded.

#### 4.2. Drinking water supply and its quality

##### 4.2.1. Table

##### 4.2.2. Drinking water quality in relation to the Czechoslovak State Norm 75-7111 - Drinking water (1987-1991)

In East Slovakia Lowland there is a shortage of drinking water of satisfactory quality. Underground waters could not be used without any treatment for excessive content of Fe, Mn and nitrogenous compounds. Infiltrated water, especially in the vicinity zone of the rivers Laborec and Ondava, was contaminated with industrial waste waters: Chemko Humenné - caprolactan, Chemko Strázske - PCB, formaldehyde, cyclosubstances, nitrogenous compounds, Bukóza Vranov nad Topľou - sulfite extracts.

After construction of sewage treatment plant and precautions in production technology, pollution decreased, but some risks last.

In individual wells at villages the main problem appears to be in nitrates with the risk of the infantile methemoglobinemia rise ( $500 \text{ mg NO}_3 \cdot \text{l}^{-1}$ ).

68.1 % inhabitants (out of which 91.3 % in towns and 33.8 % at villages) are laid on the public water-main in exposed region. In comparative region (Sobrance, Michalovce district) 45.5 % inha-

bitants are laid on the public water-main , out of which 100 % in towns (Sobrance) and 32.2 % at villages.

Main water-mains . in exposed region

- a) group water-main Starina - Košice. The source of drinking water is the water storage reservoir Starina ( $600 \text{ l.s}^{-1}$ ), which supplies especially the town Humenné and adjacent villages as well as the town Vranov nad Topľou (in the case of putting the water main for this town out of operation due to pollution of the Ondava river). There is soft water.
- b) water-main for the town Vranov nad Topľou - the water source is the Ondava river, however after contaminated from the agriculture as well as from housing quarters. It is a case of soft water with frequent microbiological defectiveness due to insufficient disinfection of treated water.
- c) water-main for the town Strážské - from the Laborec river - soft treated water.
- d) water-main Michalovce - Zemplínska Šírava - water sources are wells in the riverside zone of the Laborec river with a potential risk of industrial pollution with overlimited values of Fe and Mn in the water supply network.
- e) Boťansko-Pobodrožský group water-main . It supplies 3 towns ( Kráľovský Chlmec, Veľké kapušany, Čierna nad Tisou) and 27 villages. Water sources are the wells situated in the riverside zone of the Latorica nad Bodrog rivers. Undergroud water sources are in the town Slovenské Nové Mesto. Water is mixed, treated, and overlimited values of Fe,Mn, nitrates and oil substances are determined (1987-90). In 1991 improvement of water treatment occurred.
- f) group water-main Božčice - Sečovce - Trebišov supplies 5 municipalities, out of them 2 towns -Trebišov, Sečovce: The water quality is not satisfactory for Fe, Mn and nitrate contents.

All the given water supplies supply inhabitants with treated water!

In exposed region there are another five municipal water-mains (Brekov, Drahňov, Oborín-Kucany, Sírnik, Stankovce). Except for the water -main Stankovce, the other ones supply water with overlimited values of De,Mn and  $\text{NO}_3^-$ .

In exposed region all 9 towns (Humenné, Michalovce, Strážské, Trebišov, Kráľovský Chlmec, Veľké Kapušany, Čierna nad Tisou, Sečovce, Vranov na Topľou) are laid on the municipal water main . Out of 128 villages only 46 ones are laid on the municipal water -main and 82 villages are supplied from individual sources, predominantly with hygienically defective water, i.e. microbiologically and chemically ( $\text{NO}_3$ , Fe, Mn).

In comparative region the water supply differs from that in exposed region - towns (1) are supplied only with underground water without treatment, however in total, only 45.5 % inhabitants are laid on the municipal water-main.

- out of 54 villages 26 ones are laid on the water main. Supplying of 28 villages with drinking water is from individual sources.

. 4.3. A hygienic standard in permanently inhabited flats - table 4.3.

#### 5.0. Data on the health status of inhabitants

5.1. Standardized gross mortality-rate is not the same in the whole region monitored.

Statistically significant difference against the standard population of Slovak Republic has been found in exposed region of the Trebišov district as in men as in women.

Table 5.1.

Specific mortality-rate is elaborated according to diagnostic groups MKCH, however, has not been evaluated yet. Evaluation will be given in the report by 31st December 1992.

5.2. No statistically significant differences have been found in the parameters observed - infantile, early and neonatal death-rate, the number of stillborn children as well as incidence of congenital diseases found at birth in both exposed and comparative regions.

Table 5.2.

5.3. In table 5.2. the numbers of children with low birth weight are given. Statistically significant difference has been found in the East Slovakia Lowland, but to the detriment of the children from comparative region against those from exposed one.

5.5. Based upon the tabular review about infectious diseases (tab. 5.5.) it follows that in 1991 there were relatively large variations in the incidence of Dg among exposed areas of individual districts

as well as among comparative areas.

Responsible evaluation of people would be possible after completing reviews at least for last 5 years. It will be supplemented in the final report.

5.6. Incidence of occupational diseases in both exposed and comparative regions is given in tables.

Comparison of the incidence of occupational diseases in both regions showed 2.87-fold higher incidence of these diseases in comparative region. This fact is related with the different ratio of urban and rural inhabitants in these regions.

- in exposed region rural inhabitants (economically active) represent 38.4 %,
- in comparative region rural inhabitants (economically active) represent 78 %.

Moreover, in rural inhabitants 8.1-fold higher incidence of zoonoses (especially trichophytosis and tubercula mulgencia in agricultural workers) and 4.1-fold higher incidence of other occupational diseases (especially bronchial asthma in agricultural workers) have been recorded.

#### 5.7. Incidence of selected diseases

5.7.1. A review about the incidence of malignant tumors in 1991 is given in table 5.7.1.

Data from the district Trebišov - exposed inhabitants are not given. They will be supplemented in the next report.

From the data given in the table it follows that incidence of ZN in both exposed and comparative regions appears to be higher in rural inhabitants in comparison with urban ones.

Regarding the preliminary character of given data the statistical evaluation will be possible in the next stage of our study by standardization of incidence during several years backwards.

#### 5.7.2. Chronic bronchitis, asthma, pollinosis

The data in table 5.7.2. were elaborated on the basis of the reports of specialists of LPK (medical second opinion board). From the table it follows that the incidence of all three diseases is significantly higher in exposed region of Michalovce district than in other districts.

In remaining districts of exposed region, except for Trebišov, the incidence appears to be higher than in comparative region.

This is a fact that a lot of cases of these diseases are recorded in physicians of the first contact and not in specialized departments. E.g. in the table in the Vranov nad Topľou district the numbers of diseases given by physicians of the first contact differ from those given by the specialized departments. Except for bronchitis the total number by 31st December 1991: 663 cases, asthma 165, pollinosis 100.

From above mentioned it follows that in the next period it would be necessary to correct these data to be the most objective.

**6.0. The list of studies on the health status monitoring in relationship to environmental factors performed in the region monitored is in separate supplement.**

These are works performed by workers of the Institutes of Hygiene and Epidemiology in given districts, SIHE as well as by workers of therapeutico-prophylactic departments. It is a case of works published, but also cummulative works submitted to the Government of SR, Ministry of Health SR or other authorities.

Review of the work orientation:

- 9 works solve the problem of environmental contamination and its effect on the health status of inhabitants. The problem of PCB prevails,
- 9 works are orientated to the problem of the health status of children population in exposed region,
- 8 works are in the field of occupational medicine (especially Chemlon Humenné and Chemko Strážské)
- 15 works - from clinical departments

Elaborated: MUDr. M.Michalus, SIHE, Košice  
coordinator of the project

- based upon the data from IHE and individual departments  
od SIHE Košice

September 1992

\* spolu = ambul.starostlivosť, nem.starostlivosť, SVLZ (spoločné vyšetrovacie a liečebné zložky), liečebne, riadiaci aparát, hygienická služba

Komentár: výrazné rozdiely v nemocničnej starostlivosti sú v dôsledku rajonizácie zdravotníckych služieb, platnej aj v súčasnosti. Z dôvodov využitia prístrojovej techniky, postelovej kapacity i kvalifikovaného personálu sa nezriadovali v každom okrese všetky nemocničné oddelenia. Zabezpečenie týchto služieb zaručuje platná rajonizácia. Zvlášť špecializované služby sa poskytujú vo Fakultných nemocničiach kraja. Okres Vranov n/T je najmladší a najmenší, má neukončenú výstavbu nemocnice.

# Prehľad štúdií a prác zo sledovania zdravotného stavu obyvateľstva v znečistenej oblasti Východoslovenskej nížiny

## 1. Špecializovaný ústav hygieny a epidemiologie

Michalus, M.:

Polychlórované bifenyly (PCB) stručná charakteristika výroby, kontaminácie životného prostredia a vplyvu na zdravie v oblasti n.p. Chemko Strážske.

1988

Zpráva pre MZ SR a ČR a na celoštátnej porade krajských hygienikov.

Michalus, M. + kolektív:

Projekt A/RS/2 (Švajčiarsko-Československo)

Odstránenie znečistenia v regióne Strážske - podklady na návrhy

1991

Urbion Bratislava

Michalus, M. + kolektív

Zdravotno-hygienické zhodnotenie nadmerne znečistených oblastí Východoslovenského kraja (časť Strážske-Vranov)

1989

Účelová publikácia pre orgány VSK

Michalus, M., Lukács, Š., Porazík, I., Pajedl, I.:

Kontaminácia ŽP v oblasti Strážske a jej vplyv na zdravie.

1989

Prednesená na Spolku lekárov v Košiciach

Michalus, M. + kolektív Krajskej hygienickej stanice, Košice

Znečistenie vody chemikáliami v priestore Strážske-Michalovce

1982

Prednesené v Brne

Košlábová, M.:

Hygienická problematika kontaminácie vody chemickými látkami v priestore Strážske-Michalovce

1983

Atestačná práca

Rimár, V., Vidová, P.:

Hygienická problematika pracovného prostredia v závodoch oblasti Strážske Vranov

Michalus, M., Murárová, M.:

Extrémne znečistená oblasť Strážske-Vranov a výskyt VVCH

1991

Prednesená na krajskom seminári pediatrov

Murárová, M., Parkányi, J.:

Podiel Hygienickej služby pri ochrane zdravia a životného prostredia v nadmerne znečistených oblastiach na východnom Slovensku  
1992

prednesená na celoštátnnej konferencii v Košiciach (zborník)

Michalus, M., Murárová, M.:

Realizácia Národného programu Podpory zdravia pri ochrane ŽP  
a zdravia ľudu na východnom Slovensku  
1992

prednesená na Medzinárodnej konferencii preventívnej a sociálnej medicíny - Praha

Démantová, M.:

K niektorým otázkam sledovania zdravotného stavu detí žijúcich  
v extrémne znečistených oblastiach VSK  
1989

publikované - Bulletin KUNZ

Démantová, M.:

Výsledky sledovania zdravotného stavu detí žijúcich v extrémne  
znečistených lokalitách VSK  
1992

prednesené VŠ seminár

Démantová, M.:

Výsledky v sledovaní zdravotného stavu vybraných súborov detí  
na východnom Slovensku

1992

prednesené - Spolok lekárov

Michalus, M., Démantová M.:

Znečistenie ŽP vo VS kraji a jeho možný vplyv na výskyt vrozených  
vývojových chýb

1989

prednesené - porada gynekológov, pediatrov a pôrodníkov

Démantová, M.:

Niekteré výsledky sledovania zdravotného stavu populácie žijúcej  
vo VS regióne

1991

prednesené - VŠ seminár

Démantová, M.:

Zdravotný stav vybraných skupín detí, žijúcich v extrémne znečiste-  
ných lokalitách VSK

1989

prednesené - krajský seminár LP úseku - Vranov

Lipková, V., Bakišová, Z., Rosival, L., Liška, J..

Výsledky dlhodobého sledovania chorobnosti detí z priemyselne zne-  
čistených oblastí SSR

1988

publikované : ČS hygiena ZZ, č.3 str.153-162

- 3 -  
2. Dermatovenerologické oddelenie FNsP, Rastislavova 43, Košice

Šak, M.:

Príspevok k profesionálnym dermatózam vyvolaným chlorovanými bifenylami a k ich prevencii

1978

Habilitačná práca

Andrašina, J., Rozdobud'ková, V., Janočko, L., Šak, M.:

Vplyv PCB na niektoré zložky metabolismu u človeka pri dlhodobej expozícii

1978

Zborník prednášok "Priemyselná toxikológia"

Bilčík, P., Šak, M., Lišhák, P., Červenka, Z.:

Morfologické zmeny v pečeni potkanov po aplikácii vzorkov PCB  
1978

Zborník prednášok "Priemyselná toxikológia"

Šak, M., Lišhák, P., Červenka, Z.:

Sledovanie sérových enzymov po aplikácii komerčných zmesí PCB a ich frakcie u potkanov. s. 225-257 in

1978

Zborník prednášok "Priemyselná toxikológia"

Dom techniky SVTS Žilina

Hladká, A., Takáčová, T., Šak, M., Ahlers, I.:

Levels of Polychlorinated Biphenyls (PCB's) in Blood as Exposure Indices of Men and Animals s. 31 International Conference on Industrial and Environmental Xenobiotics.

1980

Biotransformation and Kinetics may 27-30, Prague Czechoslovakia.  
Abstracts 77 s.

Šak, M., Sitko, M.:

Sledovanie dermatotropného účinku komerčných zmesí polychlorovaných bifenylov na kožu uší králikov.

1980

Čs. Derm. 55, č.3, 191-195

Šak, M., Sitko, M., Bilčík, P.:

Účinok niektorých frakcií polychlórovaných bifenylov na kožu králikov.  
1981

Čs. Derm. č.56, č.2, 78-84.
